

# Gemcitabine

Printed from <https://www.cancerquest.org/patients/drug-reference/gemcitabine> on 05/03/2024

Brand name: Gemzar®

IUPAC: 4-amino-1-[(2R,4R,5R)-3,3-difluoro-4-hydroxy-5-(hydroxymethyl)oxolan-2-yl]pyrimidin-2-one

FDA approval: Yes

[Manufacturer Link](#)

Usage:

Malignancies for which gemcitabine is used include non-small cell lung cancer (in combination with cisplatin), pancreatic cancer (advanced or metastatic), advanced ovarian cancer (in combination with carboplatin).<sup>1</sup> Gemcitabine is administered as an intravenous infusion.

Mechanism:

Gemcitabine (Gemzar®) is an antimetabolite that acts as a pyrimidine analog. It is incorporated into a dividing cell's DNA which causes the cell to undergo apoptosis through triphosphate metabolite inhibition.<sup>1</sup>

The diagram below shows the 3D molecular structure of Gemcitabine.

Side effects:

Common side effects include bone marrow suppression, weakness, fever, nausea and vomiting, rash. Side effects may be different or more severe if gemcitabine is being administered with other cancer treatments. Gemcitabine can be a suppressor of bone marrow activity. It is important to monitor blood cell counts throughout the duration of treatment and especially before each infusion. Gemcitabine may result in toxicities of other bodily systems including the hepatic (liver), renal (kidneys), and pulmonary (lungs) systems. For this reason the function of these systems should be monitored throughout treatment to prevent severe complications. Gemcitabine should not be taken by women who are pregnant and patients should not become pregnant while using this drug, as it may have harmful effects on the developing fetus.<sup>1</sup>
