

Skin Cancer

Printed from <https://www.cancerquest.org/patients/cancer-type/skin-cancer> on 05/27/2026

Malignancies of the skin are the most commonly diagnosed cancer type worldwide.¹ The foremost cause of skin cancer remains UV radiation from sunlight. However, this disease, classically seen in older adults, is becoming increasingly common in younger populations due to tanning beds and exposure to other cancer-causing elements. Skin cancer may be classified as either non-melanoma skin cancer (cancer types include squamous cell carcinoma and basal cell carcinoma) or melanoma. The most common type of skin cancer is basal cell carcinoma. Melanoma which accounts for only 4% of skin cancer is responsible for 80% of skin cancer deaths.¹

The incidence of skin cancer is very high. It is the most common of all cancers. However, the exact numbers are not known because cases of basal cell and squamous cell skin cancers aren't always reported to cancer registries, partly because of their low lethality and very high curability rates. In 2006 it is estimated that over 2 million people were treated for non-melanoma skin cancers.² In 2023, the American Cancer Society estimates that there will be 97,10 new cases of melanoma and 7,320 new cases of other non-epithelial skin cancer, with 7,990 melanoma-related deaths and 4,480 deaths from other non-epithelial skin cancers.³

Young men DO get cancer. View the clip and then [watch an interview](#) with Philip Groom, a skin cancer survivor diagnosed when he was 16 years old.

Skin Cancer Education:

CancerQuest, with help from the Melanoma Group at the [Winship Cancer Institute of Emory University](#), has developed a skin cancer curriculum. The curriculum is available **free** for educational (non-profit) uses. [View/Download the curriculum.](#)

Anatomy Of The Skin

The skin is one of the largest organs of the body⁴ and is responsible for providing protection to the other systems of the body. Skin prevents water loss and dehydration, shields the internal organs in the event of injury, regulates body temperature, senses outside stimuli such as touch as well as heat and cold, and serves as a barrier to infection.⁵ As seen below, the skin is made up of three layers: the outer epidermis, the dermis and the deep subcutis layer. Other important elements of the skin include: hair follicles, sweat glands and nerve endings. Hair follicles protrude into the dermis layer and help regulate body temperature. Microscopic pores on the surface of the skin are connected to sweat glands which also help maintain homeostasis.

The pigments that color skin are produced by cells called melanocytes. Melanocytes, located in the epidermis (specifically in the stratum basale as seen in the diagram above), synthesize melanin which determines the color of

the skin, hair and eyes.⁶ An individual's skin color is determined by their genes and their environment (primarily sun exposure). Our skin can change color in reaction to sun exposure. This is called the "tanning response." When skin absorbs UV radiation, melanin is produced and transferred to keratinocytes altering (darkening) the color of the skin.⁷ Melanin in the skin absorbs and scatters UV radiation entering the body and helps protect the skin from adverse reactions to radiation, such as DNA damage (gene mutation). Viewed this way, the "tanning response" is really a defensive reaction by the body to the presence of damaging radiation.⁶

Types Of

Skin cancer may be divided into two types: non-melanoma and melanoma.

Non-melanoma Skin Cancer

There are two major sub-types of non-melanoma skin cancer:

- **Basal Cell Carcinoma**- The most commonly diagnosed skin cancer. Tumors often develop on regions of the body that receive regular sun exposure such as the face and hands. Due to its slow growth rate, basal cell carcinoma rarely spreads and is usually treatable.⁸ A common form of basal cell carcinoma is nodular basal cell. Lesions appear as pearly nodules in various colors including brown, black and blue.⁹

Some examples:

Images used courtesy of the [Skin Cancer Foundation](#)

- **Squamous Cell Carcinoma**- Appears on body parts that experience increased levels of sun exposure such as the face, lips and back.⁸ This cancer is more likely to spread than basal cell carcinoma. The cancerous lesions have numerous forms. They may be rough, scaly, lumpy or flat. Blood vessels may appear at the edge of a lesion causing it to bleed easily.⁸

Some examples:

Images used courtesy of the [Skin Cancer Foundation](#).

Melanoma Skin Cancer

Melanoma is a cancerous growth of melanocytes and most frequently develops in the skin.¹ Melanoma may also develop in other parts of the body that contain melanocytes including the meninges, the digestive tract, the eyes and lymph nodes. The following descriptions are limited to melanoma of the skin.

There are several types of melanoma that can be categorized based on their appearance, either with the naked eye or microscopically:

1. *Superficial spreading*: The most frequently observed melanoma. This form may develop in any region of the skin. Lesions are usually raised around the edges and a brown color with hints of pink, white, gray and blue.
2. *Nodular type lesions*: Also arise on all regions of the body and are typically black or brown in color.
3. *Acral lentiginous lesions*: Characterized by flat, brown or black tumors that often develop on the hands and feet.
4. *Lentigo maligna melanoma*: Develop on an individual's face. Distinguished by its irregular border and tan to brown color.¹⁰

Some examples of melanomas that demonstrate the irregular shapes and colors often encountered:

Images used courtesy of the [Skin Cancer Foundation](#).

Risk Factors

The following risk factors that influence one's risk of developing skin cancer are discussed below:

- Ultraviolet Radiation¹
- Skin Color¹⁰
- Sun Sensitivity
- Immunosuppression
- Prior Diagnosis⁹
- Family History

- Radiation Therapy[11](#)
- Smoking[8](#)
- Chemical Exposure[8](#)
- Drugs used to treat other conditions[12](#)
- Injury[8](#)
- Geographic Location
- Infection with HPV?[13](#)

Ultraviolet Radiation

Overexposure to ultraviolet (UV) radiation may cause genetic changes (mutations) in skin cells. The genetic changes cause the affected cells to alter their behavior and may result in cancer.[1](#) Sources of UV radiation include the sun and tanning beds. Ultraviolet radiation also induces the production of very reactive chemicals, oxidants, in affected cells.[1](#) Oxidants cause some of the changes associated with aging and increase one's risk of developing cancer.

Tanning beds are a dangerous source of UV radiation. They have been associated with all major types of skin cancer - basal cell carcinoma, squamous cell carcinoma, and melanoma. Tanning beds have been designated as a cancer causing agent by the World Health Organization.[14](#), [15](#) The use of a tanning bed increases a person's risk of developing melanoma, regardless of whether the person gets sunburned.[16](#)

Below is a diagram showing the radiation from the sun and which parts make it to the surface of the earth. This graphic is interactive, so click on the different boxes to see the penetration of different types of light (including UV) and to see the layers of the atmosphere.

Skin Color & Sun Sensitivity

Fair skin is more susceptible to ultraviolet radiation damage.[10](#) Caucasians, specifically individuals with freckles, light eyes and/or red hair, are at higher risk of skin damage that may lead to skin cancer.[10](#)

Immunosuppression

Immunosuppressants weaken the action and efficacy of the immune system and hinder its ability to fight foreign invasion. [1](#)Immunosuppression may support the development of cancer. A weakened immune system is less able to eliminate cells that have suffered mutations and have the potential to develop into cancer cells. In addition, immunosuppressant therapies may have direct cancer causing consequences.[17](#)

Drugs used to treat other illnesses

Thiopurines, a class of drugs used to treat inflammatory diseases (i.e. Crohn's disease and inflammatory bowel syndrome) and some forms of cancer, have been shown to increase the risk for the development of non-melanoma skin cancers.[12](#)

Personal History

Survivors of skin cancer have an increased risk of developing a secondary cancer.[1](#) The greatest risk for relapse is within the first five years following treatment. This heightened risk may be a result of a biological predisposition, previous exposure to skin cancer risks or a consequence of the initial cancer treatment itself.

Radiation Therapy

Radiation therapy is often used in the medical field in the treatment of primary cancers. Irradiation of primary tumors often exposes normal skin to increased levels of radiation and may lead to the development of secondary cancers, including skin cancer. The cancers arise due to mutations within skin cells caused by high doses of radiation.[11](#)

Chemical Exposure

Chronic exposure to arsenic, industrial tar and paraffin may increase one's risk of developing skin cancer.[8](#)

Serious injury

In some instances, skin cancer development is associated with serious injury or inflammation.[8](#) Malignant growths that arise at sites of previous serious/chronic wounds such as burns and pressure ulcers are termed Marjolin ulcers.[18](#)

Risk Factors For Melanoma

Risk factors specific to melanoma:

- Sun Burn
- Prior Diagnosis[1](#)
- Family History[10](#)
- Melanocytic Nevi[10](#)

Watch the video below to learn about some great skin cancer prevention tips. [Watch the full interview with Dr. Suephy Chen.](#)

Sun exposure:

Sun exposure increases one's risk of skin cancer. Individuals are inevitably exposed to sunlight, or ultraviolet radiation, during their daily activities. However, certain outdoor behaviors elevate an individual's likelihood of developing cancer. Infrequent, but intense exposure to sunlight during childhood increases one's risk of developing melanoma. [1](#) Melanoma is often observed in areas of the body that receive infrequent but intense sun exposure such as the neck and the back of the legs.[19](#)

Also, it is important to note that cutaneous melanoma may occur in regions of the body typically shielded from sunlight such as the groin and bottom of the feet.

Family History

Individuals who have first degree relatives, including parents, siblings or children, diagnosed with melanoma have an 8 to 12 fold increased chance of developing melanoma. [10](#) This increased risk is likely due to a biological predisposition to cancer development.

Melanocytic Nevi

The medical term for a marking on the skin, such as a mole or birthmark, is "nevus" (plural-nevi). Most melanocytic nevi develop during childhood and adolescence as a result of sunburn and sun exposure. The presence of melanocytic nevi is associated with an increased risk of developing melanoma.[10](#)

Symptoms And Detection

The American Academy of Dermatology and the American Cancer Society recommend that individuals perform monthly self-examinations.[10](#) It is important to keep the **ABCDE's** (**A**symmetry, **B**order, **C**olor, **D**iameter, **E**volution) of melanoma in mind.:

- **Asymmetry:** melanomas tend to be asymmetrical while benign lesions are more rounded and symmetric.
- **Borders:** Benign lesions are usually regular and flush with the skin while melanomas may have irregular and/or raised borders.

- **Color:** Melanomas may be tan, black or brown and often include regions of red, white and blue.
- **Diameter:** In general, melanomas are larger than 6 mm in diameter.
- **Evolution:** Changes in physical appearance of melanocytic growths are often observed over time and skin marking should be monitored for changes. Because the changes may be gradual, it is a good idea to photograph any suspicious marks, including a ruler or coin for size comparison. This allows for a direct comparison of images taken at different times.

Although the ABCDE guidelines assist with a valuable screening tool, **it is important to see a physician regularly and especially if one finds a suspicious or irregular skin marking/growth or witnesses a change in an existing skin marking/growth.**[10](#)

Melanoma Staging

Pathology Report & Staging

Staging is a powerful tool for treatment plan development and risk assessment in individual patients. Staging also enables physicians to communicate with each other regarding patients' diseases and ensure equal standards of care for patients with similar disease states. [20](#)The American Joint Committee on Cancer (AJCC) has developed a staging system for nonmelanoma and melanoma skin cancer.[10](#)

Staging of skin cancer is based on the TNM staging described in the CancerQuest section on [Cancer Staging](#). Using this information, physicians may determine the stage of disease. The information below is specific for melanoma:

- **Stage I:** The disease is localized to a primary tumor site. The majority of diagnoses are during this stage.[20](#)
- **Stage II:** The disease is more developed, but remains localized to the original site.[21](#)
- **Stage III:** The disease has spread regionally; doctors often examine the number and location of invaded lymph nodes.[20](#)
- **Stage IV:** The melanoma has spread to distant organs.[20](#)

Several different approaches to staging of melanoma have been developed. Two criteria that have been used extensively include the categorization of melanomas according to their 'Clarks' levels' or 'Breslow thickness'. The Clark level is based on the layers of epidermis that the tumor has penetrated at the time of measurement. Breslow thickness measures the absolute distance of tumor penetration into the epidermis (measured in millimeters (mm)).

The Breslow tumor thickness evaluation system measures tumor thickness in mm from the top of the granular layer to the deepest tumor growth. The Breslow scale divides melanomas into four classes:

- T1 1mm or less; "Thin melanoma"
- T2 1-2 mm
- T3 2-4 mm
- T4 greater than 4mm depth; "Thick lesions"[22](#), [23](#)

The "Clark levels of invasion" system, named after the developer, pathologist, Wallace Clark, was the first widely accepted method for staging of melanomas. It is considered a reliable staging system today, and tumors are classified as one of five categories. **It is important to note that Clark levels are *NOT* the same as the stage of the disease.**

- Level I Lesions: Melanoma restricted to the epidermis also known as an in situ melanoma.
- Level II Lesions: Melanoma crosses the epidermis and invades the papillary dermis. This may be referred to as the micro-invasive radial growth phase.
- Level III Lesions: The entry into the true tumor phase in which the tumor grows to fill the papillary dermis region. Such tumors have entered the vertical growth phase.

- Level IV Lesions: Tumor cells overcome barriers of the papillary dermis- reticular dermis barrier, invading the reticular dermis region.
- Level V Lesions: Tumor growth extends into the subcutaneous fat.[22](#), [23](#)

More advanced disease is generally associated with a decreased survival rate.[20](#)

View detailed staging information from the [National Comprehensive Cancer Network \(NCCN\)](#).

Tumor Biology

Genetic changes that occur in cancer cells include mutation of key regulatory genes, changes in protein products, and changes in the *amount* of product produced by genes (gene expression). As changes accumulate, cells become more abnormal and cancer may result. Details of genetic change associated with cancer can be found in the [Mutation](#) section. Some of the genetic elements that have been shown to be important in the development of skin cancer are discussed below:

MC1R Gene and α -melanocyte-stimulating hormone

The melanocortin receptor is responsible for binding alpha-melanocyte-stimulating hormone, the signal that initiates melanin production. Fair-skinned individuals have polymorphisms that reduce the affinity of MC1R resulting in decreased MC1R:alpha-MSH binding. As a result, melanin production is reduced, increasing the individual's risk of developing melanoma.[24](#)

CDKN2A

CDKN2A refers to a region of DNA coding for two tumor suppressor proteins: Ink4A and Arf. Both proteins play a key role in cell cycle regulation. Reduced activity of these proteins has severe consequences on the ability of cells to regulate cell division. Mutations in CDKN2A result in reduced function of the p53 and RB tumor suppressor pathways.[25](#)

RAS Genes

RAS refers to a group of genes that are often mutated in cancer of many different types, melanoma included. The protein products are involved in transmitting signals through cells (also called "signal transduction") and are involved in numerous processes. Mutated RAS may increase malignant cell proliferation and reduce apoptosis. The pathways controlled by RAS have been found to be very frequently disrupted in melanoma cells.[25](#)

RAF Genes

The products of the three known RAF genes (RAF-1, ARAF and BRAF) function in the RAS pathway. The proteins are serine/threonine kinases and they function to transmit signals through the cell, influencing cell division. The BRAF gene product also seems to be involved in cell death (apoptosis). In one study, mutations in BRAF genes were observed in 66% of melanoma cell lines examined.[25](#), [26](#)

Bcl-2

This gene encodes a protein that regulates apoptosis. Mutations that increase the expression of Bcl-2 or enhance its function tend to reduce cell death and favor cancer development.[25](#)

Treatment

Both surgical and non-surgical approaches are used in the treatment of melanoma and non-melanoma skin cancers. [9](#)Treatment of non-melanoma skin cancer is made more difficult by the high frequency of recurrence. [27](#)For advanced melanoma, a highly successful treatment option for advanced disease has not yet to be identified.[27](#)

Surgical Treatment

Excision of a skin cancer lesion is a frequent treatment option. Excision may be curative for diseases that are in stages I or II (localized).[10](#)

- [Learn about surgical treatment of cancer cells](#)
- [Watch an interview with skin cancer specialist Dr. Suephy Chen.](#)

Non-surgical Treatment

Alternate treatment methods are preferred for patients whose health does not allow them to enter into surgery or for patients with cancerous lesions located in regions difficult to access surgically. Patients who undergo surgery may receive additional treatments. [27](#)Examples of nonsurgical treatment options include:

- **Radiotherapy** - the use of high energy waves, such as x-rays, to kill cancer cells.

[Learn more about radiotherapy.](#)

- **Photodynamic Therapy** - a type of treatment in which an "inactive" medication is applied to the area of interest and then "activated" by exposure to specific wavelengths of light. In the case of skin cancer, the agent may be applied directly to the skin in the form of a liquid.[28](#)
- **Topical Drug Treatments:** an ointment containing imiquimod (Aldara™) has been used to treat basal cell carcinoma, genital warts and actinic keratosis. Imiquimod is an immune response modifier that stimulates the immune system to eliminate cancer cells. [View the package insert.](#)

[Learn about the immune response and cancer.](#)

[Learn more about Aldara™ from the manufacturer.](#)

- **Biological Treatments:** biological treatments for melanoma include the use of interleukin 2 (IL-2).

[Learn about biological response modifiers and cancer.](#)

- **Specific Inhibitors:** Kinase inhibitors, including sorafenib (Nexavar®) are being evaluated for treatment of advanced melanoma.

Section Summary

Introduction

- Malignancies of the skin are the most commonly diagnosed cancer type worldwide.
- Skin cancer is becoming increasingly common in younger populations.

Types of Skin Cancer

- Skin cancer can be divided into two types: melanoma and non-melanoma.
- Non-melanoma skin cancer has two major subtypes: basal cell carcinoma (BCC) and squamous cell carcinoma (SCC).
- Basal cell carcinoma is the most commonly diagnosed skin cancer.
- Melanoma is a cancerous growth of melanocytes and most frequently develops in the skin.

Risk Factors

- Overexposure to UV radiation causes genetic damage that can promote skin cancer development.
- Fair skin is more susceptible to ultraviolet radiation damage.
- Survivors of skin cancer have an increased risk of developing a second cancer.
- Exposure to certain chemicals and radiation increases the risk for skin cancer.

Symptoms and Detection

- The ABCDEs of skin cancer assist in early detection: Asymmetry, Border, Color, Diameter, Evolution

Pathology Report and Staging

- T/N/M staging is used in skin cancer. This system assigns a degree of severity based on size, lymph node involvement, and spread of the cancer.
- Other skin cancer staging systems consider the depth of penetration of the tumor into the epidermis.

Skin Cancer Tumor Biology

- Many genetic changes occur in cancer. Details can be found in the [Mutation](#) section.
- Genes that have been implicated in the development of skin cancer include MC1R, CDKN2A, RAS, RAF, and Bcl-2.

Treatment

- BCC and SCC are frequently removed via minor surgery.
- Early-stage melanomas can be surgically removed.
- Non-surgical treatments for skin cancer include: chemotherapy, radiotherapy, topical drug treatments, biological treatments and specific inhibitors.

Know The Flow: Melanoma

Know the Flow is an educational game for you to test your knowledge. To play:

- Drag the appropriate choices from the column on the right and place them in order in the boxes on the left. Note that you will only use five of the six choices to complete the game.
- When done, click on 'Check' to see how many you got correct.
- For incorrect answers, click on 'Description' to review information about the processes.
- To try again, choose 'Reset' and start over.
